Damping-off (047)

Photo 1. Onion seedlings attacked before emerging through the soil and afterwards. An example of pre- and post-damping-off. (Germination of the seed was high!)

Photo 2. Cabbage seedlings have been attacked at the junction of stem and soil, a case of post-emergence damping-off.

Photo 3. Damping-off in Chinese cabbage. When plants are sown thickly like this it encourages spread of the disease.

Common Name

Damping-off

Scientific Name

Commonly, *Pythium* and *Rhizoctonia* are involved, but *Fusarium* and *Phytophthora* may also cause similar diseases. Note, *Pythium* and *Phytophthora* are not fungi but water moulds or oomycetes, related to algae.

Distribution

Worldwide. The fungi that frequently cause damping-off are present throughout Oceania, so it is expected that damping-off will be common in the region.

Hosts

Many kinds of fruit and vegetable seedlings show the disease in the nursery, with beans, cabbage, carrot, lettuce, onion, and tomato especially susceptible.

Symptoms & Life Cycle

The fungi and water moulds involved in damping off are widely distributed in soil. They live on organic matter, but also on the roots of living plants as parasites. *Pythium* and *Phytophthora* prefer wet soil conditions, and have spores that swim in soil water. By contrast, *Rhizoctonia* and *Fusarium*, do not survive well in wet soils.

Seedlings are attacked by damping-off fungi and water moulds (*Pythium* and *Phytophthora* are not fungi) either before they emerge (called pre-emergence damping off) or after (called post-emergence damping off) (Photos 1-3).

Plants that are growing poorly, because the soil is waterlogged or the temperature is unsuitable, are more likely to be infected by damping-off fungi and water moulds, in contrast to those seedlings growing rapidly.

Spread of these fungi and water moulds occurs in water splash, on contaminated tools, in potting mixes and in the roots of infected plants.

Impact

Damping-off is a serious disease affecting most seedlings of vegetables. There are two kinds: (i) pre-emergence damping off results in gaps in the rows of seedlings, whereas (ii) post-emergence damping off results in seedlings that fall over due to root rots and stem infections, often at soil level. Those that survive the attack may be stunted, or grow slowly.

Seedlings that have strong stems, such as cabbages, do not always fall over; the plants have thin, twisted, discoloured stems (known as "wire stem"). If the infection girdles the stem, the seedlings die eventually.

Detection & inspection

Look for gaps in the row and, if present, look to see if the seed is decayed. Look for seedlings that have emerged and then fallen over due to soft rots on the stem or decayed roots. Look for lesions and cankers (open lesions) on seedlings with strong stems. Threads of fungi (e.g., *Rhizoctonia*) and water moulds (e.g., *Pythium* and *Phytophthora*) may be present over the soil and seedlings, and visible with the naked eye.

Management

CULTURAL CONTROL

Cultural control is important. The following should be done:

- Sterilise the soil mix:
 - Heat the soil in an earth oven over hot stones covered in leaves or sacks for at least one hour, or
 - Place the soil mix in boxes or place it on the ground between bamboo sections, and pour boiling water over the soil.
- Keep the treated soil in clean bags until it is used, to prevent reinfection from water splash or contaminated tools.
- If outbreaks of damping-off occur in seedbeds, move the beds to a different site.
- Water soil and plants with rain water, not with water from ponds or streams.
- Do not overwater seedlings; ensure the seed boxes have good drainage.
- Raise nursery seed boxes above ground level (at least 1 m) to avoid rain splash from the soil.
- Always use a nutritious soil mix: rotten coconut mixed with soil is best. If using home-made compost (from household scraps and/or "green" matter) make sure it is well rotted before mixing it with the grated coconut.

RESISTANT VARIETIES

It is unlikely that any of the common vegetable varieties would differ in their susceptibility to damping-off.

CHEMICAL CONTROL

If cultural controls fail, treat seed with a fungicide, such as mancozeb, or thiram. Fungicide can also be used to treat seedbeds and/or seed boxes. Bleach can also be used to sterilise pots and seedboxes; dilute to about 1% sodium hypochlorite, and wash well after treatment.
