Bele (Abelmoschus) flea beetle (022)

Photo 1. Extensive damage on leaves of *bele* by *Nisotra basselae*, such that growers in many parts of Solomon Islands have abandoned its cultivation.

Photo 2. Adult *Nisotra basselae* on *bele*.

Diagram. Life cycle of *Nisotra basselae*.

Common Name

There is no common name, but bele flea beetle, Abelmoschus flea beetle, aibika flea beetle sliperi kabis flea beetle would all be suitable.

Scientific Name

Nisotra basselae

Distribution

Narrow. The beetle is endemic to Papua New Guinea, and in 1984 spread to Solomon Islands.

Hosts

Bele (*aibika*, *sliperi kabis*, island cabbage, *Abelmoschus manihot*), possibly *Hibiscus tilaceous* (under lab conditions, but not seen in the field); not on *Sida*, nor the garden hibiscus, *Hibiscus rosa-sinensis*.

Symptoms & Life Cycle

Adult beetles feed on leaves creating many small (1-5 mm diameter) holes (Photo 1). Eggs are laid singly or in small batches just below the surface of the soil, near the stem. They hatch after 8-9 days, and the larvae remain in the soil for 12-18 days feeding on small roots. They moult twice before they pupate for 4-6 days. Adults emerge from the soil (Photo 2). Males emerge first, taking 6-8 days to become sexually mature; females take 3-5 days. The entire life cycle takes about 40 days (Diagram). The adults disperse by walking, jumping and flying. The number of generations per year is unknown.

Impact

The damage is so severe that in many places in Solomon Islands people have stopped growing *bele*. The larvae feed on small roots, especially the tiny root hairs. Whether this affects the growth of the plant is unknown.

Detection & inspection

Look for small holes in the leaves and the presence of beetles. The adult beetles are about 4 mm long and can be found on both sides of the leaves. The head and part of the section below are orange/brown, and the wing cases are black. The beetles are less obvious during the hotter times of the day, when they move under the leaves.

Management

QUARANTINE

Some of the more isolated parts of the Solomon Islands are free from the beetle, e.g., the provinces of Rennell and Bellona, and Temotu. Therefore, no leaves of *bele* or other parts of the plant should be taken there. Extension services should constantly remind people of this, with messages on radio and in newspapers.

NATURAL ENEMIES

Parasites of the adults include nematode worms and mites. The adults do not seem to be affected by the presence of the fire ant, *Wasmannia auropunctata*. *Nisotra* may be toxic to visual predators, like birds and lizards.

CULTURAL CONTROL

There are a number of possibilities:

Before planting:

- Plant *bele* far from plants infested with the beetle; the beetles do not fly long distances.
- There is some evidence that planting in clover reduces infestations.
- Plants grown under shade may have fewer beetles; however, too much shade gives poor plant growth.
- Plant more *bele* in the wet season when beetle numbers are lower.

During growth:

- Hand pick the beetles when infestations have just started; this will delay beetle populations reaching damaging numbers later.
- Cultivate the soil at the base of the plants to expose eggs, larvae and pupae to the sun and predators.
- Apply thick mulches of straw, sacks, grass or other organic materials (several centimetres thick); these may prevent female beetles from laying eggs at the base of the stems.
- Use horticultural glue bands around the stems. The glue is a non-drying sticky substance made from natural gum resins, vegetable oil and wax that prevents crawling insects from reaching the soil. One such product is called "Tanglefoot".

After harvest:

- Collect debris and burn it when plants have become old and harvests of leaves are no longer worthwhile.

CHEMICAL CONTROL

- Use plant-derived products, such as derris, pyrethrum or chilli (with the addition of soap).
- Note, a variety of *Derris*, brought many years ago to Solomon Islands from Papua New Guinea, is effective as a spray. It contains rotenone, an insecticide, so it should be used with caution. There may be varieties of *Derris* (fish poisons) in your country that can be tried (see **Fact Sheet no. 56**).
- Orthene (acephate) is used in Solomon Islands; other insecticides, such as synthetic pyrethroids are likely to be effective and safer.
