Bele (*Abelmoschus*) shoot borer (023)

Photo 1. Caterpillar of *Earias vittella* in the stem of *bele*. Note it is brown with orange spots.

Photo 2. Stem of *bele* split open to show a caterpillar of *Earias vittella*, and the frass that it pushes out through the entrance hole.

Photo 3. Damage to okra (*Abelmoschus esculentus*) by the bele shoot borer, *Earias vittella*.

Photo 4. Wilt of *bele* caused by *Earias vittella*.

Photo 5. Wilt of *bele* caused by *Earias vittella*.

Photo 6. Hole in the stem of *bele* made by *Earias vittella* (beneath the thumb).

Photo 7. Adult bele shoot borer, *Earias vittella*.

Common Name

Bele shoot borer, spotted bollworm, spiny bollworm

Scientific Name

Earias vittella

Distribution

Worldwide. Asia, Africa, Oceania. It is recorded from Australia, Fiji, Guam, Federated States of Micronesia, Northern Mariana Islands, Palau, Papua New Guinea, Samoa, Solomon Islands, Tonga, and Vanuatu.

Hosts

The caterpillar attacks *bele* (*aibika*, *sliperi kabis*, island cabbage, *Abelmoschus manihot*), okra, hibiscus, and tomato.

Symptoms & Life Cycle

Caterpillars do the damage by feeding inside the stems (Photos 1-3). The tips and leaves wilt and die (Photos 4&5). Caterpillars also feed inside fruits and pods of cotton and okra. Adult moths lay eggs at night, singly, on shoots, buds and young fruit.

Eggs are light blue-green, round, and about 0.5 mm across. They gradually change to brown just before hatching; they hatch into caterpillars in the early morning, after 3-7 days. The caterpillars may move some distance before boring into the soft growing parts of the plant to feed (Photo 6). They are grey-brown with orange spots and a black head. The body is up to 18 mm long and 3 mm wide, with two pairs of fleshy bumps on each body segment. They are full-grown after 9-17 days.

Mature caterpillars spin a silken cocoon, which is brown, felt-like, and shaped like an upside-down boat. Cocoons are fastened to the plant, to debris on the ground, or within cracks up to 30 cm deep in the soil. Inside the cocoon, the caterpillar turns into a pupa that is about 13 mm long, with three small spikes on its tail. The pupa lasts for 1-2 weeks, before it splits open and an adult moth emerges.

Adults live for up to 1 month, feed on nectar, and lay up to 500 eggs. Adults are 12 mm long, with a wingspan of about 20 mm (Photo 7). They are mostly white, with a central green wedge pattern running along their front wings.

Impact

In Fiji, there are reports of the shoot borer destroying about 20% of the okra crop, and in India it is a major pest of cotton bolls. In Solomon Islands, it is the most common concern of farmers attending plant health clinics.

Detection & inspection

Look at the stem tips and leaves to see if they are wilting and dying. Look closely for small holes in the stem below the dying tip. The caterpillars push their waste (frass) out of these holes, and this is often very noticeable (Photo 5). Break the stem near this hole to find the caterpillar in its tunnel.

Management

NATURAL ENEMIES

Small wasps attack the eggs, caterpillars and pupae, and lacewings and ladybird beetles eat the eggs. It is important to think about these natural enemies when considering how to control *Earias*. If insecticides are used, choose ones that do not kill these beneficial insects. Preferably, use those that are allowed under organic vegetable production.

CULTURAL CONTROL

Before planting:

- *Earias* is less abundant during wet, humid weather; therefore, growing crops during the wet season may be effective.

During growth:

- When shoots wilt, look for the hole in the stem (Photo 5) and cut out the shoot several centimetres below it, making sure that the caterpillar has been removed.
- There are no known resistant varieties in Pacific island countries; however, look carefully to see if some types are less attacked than others, and plant more of those.

After harvest:

- After harvest, and if plants are severely attacked, pull them all out and burn them; stop growing the cabbage for a few weeks, and then plant the crop in a new garden.

CHEMICAL CONTROL

Populations of *Earias* tend to build up slowly, so only two or three applications of pesticide may be needed to reduce numbers in a crop.

- Use neem, derris, pyrethrum or chilli. If these are used, add soap to help the chemical reach the caterpillars within the shoots.
- Alternatively, use commercial biopesticides, e.g., spinosad (the product is called Success) or Bt - *Bacillus thuringiensis* var. *kurstaki* (the product is called Dipel).
- If using Dipel, note the following:
 - Ensure that Bt covers the plants; caterpillars will only die if they eat Bt.
 - Eggs are not susceptible to Bt.
 - Use Bt as soon as damage is seen.
 - Small larvae are more susceptible to Bt than fully grown ones.
- Synthetic pyrethroids are likely to be effective, but will also kill natural enemies.
