Citrus rust mite (344)

Photo 1. Citrus rust mite, *Phyllocoptruta oleivora*, on limes, clearly showing the contrast between the damaged and healthy parts of the fruit.

Photo 2. Citrus rust mite, *Phyllocoptruta oleivora*, damage on an orange.

Photo 2. Adult citrus rust mite, *Phyllocoptruta oleivora*.

Common Name

Citrus rust mite

Scientific Name

Phyllocoptruta oleivora; previously known as *Eriophyes oleivorus*.

Distribution

Worldwide. Asia, Africa, North, South and Central America, the Caribbean, Europe, Oceania. It is recorded from Australia, Cook Islands, Fiji¹, and New Zealand.

Hosts

Citrus species.

Symptoms & Life Cycle

A microscopic mite does the damage; it feeds on the rind of fruit killing the cells causing the fruit to become slightly rough, and turn silvery (grapefruit and lemons) (Photo 1), reddish or black (oranges) (Photo 2). The fruit may be smaller than usual, and do not store well. In heavy infestations, leaves and green twigs bronze, and trees are less vigorous. The mites prefer the side of the fruit facing the sun; consequently, fruit damage is greater on the outside of the tree.

Feamles lay about 30 eggs singly in pits or depressions in the leaves and fruit, or in cracks in the bark. The nymphs are similar to the adults, but paler and slimmer. The adults are yellow to yellow-brown, wedge or spindle-shaped, with two pairs of legs (Photo 2).

The female is about 0.15 mm long, slightly longer than the males, and too small to be seen with the unaided eye. The life cycle is from 7 to 10 days depending on the temperature. The mites prefer warm, humid weather.

Spread occurs locally in rain splash, and over greater distances on wind currents, birds, insects, machinery, and clothing of human beings. It also spreads with the trade in plants and plant parts, both domestically and internationally.

Impact

Considered an important pest in some countries (e.g., Australia, Argentina, China, Egypt) as it can reduce size, weight and quality of fruit, juice content, and increase fruit drop.

Detection & inspection

Look for the mites using a hand lens (x10 or higher magnification). Examine small fruit on inside of the canopy, looking at the stem end of the fruit, in particular. Look to see if the mites are all over the fruit; if so, numbers of mites are high. If damage is seen, that means that large numbers of mites are present already, and it may be too late to spray.

Management

NATURAL ENEMIES

Predatory mites, *Amblyseius* species, keep population of the citrus rust mite in check. They are off-white, much larger than the citrus rust mite, up to 0.4 mm, and can be seen with the naked eye along the side of veins, or under the calyx of the fruit (leaves at the stalk end). Predators, such as ladybird beetles are less effective until mites are numerous.

CHEMICAL CONTROL

Only consider using a pesticide before there are large infestations. But note, spraying will kill predatory mites and may upset biological control and make the situation worse. Only spray those trees where the infestation needs to be brought under control, not every tree if there is no need.

If pesticides are needed consider the following:

- Use lime sulphur (polysulphide sulphur) or wettable sulphur; leave at least 30 days between spraying lime sulphur and sprays of oil. Take care to follow manufactures' instructions as sulphur can burn the leaves.
- Alternatively, use white oil (made from vegetable oils), soap solution, or horticultural oil (made from petroleum) (**see Fact Sheet no. 56**).
 - White oil:
 - 3 tablespoons (1/3 cup) cooking oil in 4 litres water.
 - 1/2 teaspoon detergent soap.
 - Shake well and use.
 - Soap:
 - Use soap (pure soap, not detergent).
 - 5 tablespoons of soap in 4 litres water, **OR**
 - 2 tablespoons of dish washing liquid in 4 litres water.
- Commercial horticultural oil can also be used. Usually, mite infestations are controlled using a number of low concentration (0.25-0.5%) oil sprays. White oil, soap and horticultural oil sprays work by blocking the breathing holes of insects and mites causing suffocation and death. There may be changes to feeding and egg-laying behaviour. Spray the undersides of leaves; the oils must contact the mites. A second application of soap or oils may be necessary after 3-4 weeks.
- *Be careful to follow manufacturers' instructions if using a commercial horticultural oil or a white oil.* Do not apply oils where temperatures are higher than 35°C or where trees are moisture-stressed. Never mix with other pesticides without checking compatibility.
- Alternatively, use abamectin, a miticide/insecticide, made from a soil bacterium.
