Lettuce *Sclerotinia* collar rot (129)

Photo 1. *Sclerotinia* on soybean. Note the fungus has destroyed the roots of these three plants, and large balls of the fungus called sclerotia have formed on the stem and tap root. These will germinate to produce a mushroom-like body that produces spores.

Photo 2. Severe wilt of lettuce caused by *Sclerotinia* soft rot fungus. The fungus produces sclerotia (see Photo 1) and these can survive in the soil for many years.

Photo 3. Close up of lettuce showing the basal rot, with the cottony growth of the soft-rot fungus, *Sclerotinia*.

Common Name

Cottony soft rot, *Sclerotinia* soft rot, collar rot, white mould, lettuce drop.

Scientific Name

Sclerotinia sclerotiorum

Distribution

Worldwide. Asia, Africa, North, South and Central America, the Caribbean (restricted), Europe, Oceania. It is recorded from American Samoa (tomato), Australia (bean, watercress, lettuce, potato), Cook Islands (capsicum), Fiji (bean, carrot, lettuce), Samoa (bean), and Tonga (bean).

Hosts

Wide range of vegetables (beans, cabbage, capsicum, celery, lettuce, peanut, potato, tomato), fruit and field crops (sunflower). More than 75 plant families are hosts.

Symptoms & Life Cycle

The fungus infects roots, causing rots and basal stem cankers, as well as aboveground parts causing rots to leaves, stems and fruit. It is also a cause of seedling damping-off.

Sclerotinia produces large amounts of cottony growth over rots on stems, leaves and flowers. Large, black, irregular bodies, up to 20 mm long and 7 mm wide, are formed on or in the rots; these are called 'sclerotia' (Photo 1). Sclerotia allow the fungus to survive for many years in the soil. Eventually, the sclerotia germinate in cool, moist (foggy) weather producing small (3-8 mm diameter), cup-shaped, cream, mushroom-like bodies. These contain spores, which are forced out and carried by wind to dying leaves and flowers where they germinate, grow and infect healthy parts of the plant.

Temperatures just below 20°C are best for infection; that is why the disease is not common in the tropics, except in cool wet places.

Impact

Sclerotinia is a fungus that is more common in temperate and sub-tropical countries rather than those in the tropics. It attacks beans, cabbage, carrot, cauliflower, lettuce (Photos 2&3), lucerne, pea, peanut, potato, rapeseed, soybean (Photo 1), sunflower, tomato and more. Crop losses in the field range from negligible to 100%. Losses also occur in transit and storage. Apart from losses in yield, the disease also affects quality.

Detection & inspection

Look for the thick, white, cottony growth over leaves, stems, flowers and fruit; this could be mistaken for *Pythium* cottony leak (**see Fact Sheet no. 128**), so look for the characteristic black irregular-shaped sclerotia on or in the rots. Split stems open, e.g., tomato, to find the sclerotia inside.

Management

CULTURAL CONTROL

Before planting:

- *Choice of varieties*: If the disease persists on beans, use staked climbing varieties rather than short bush types.
- *Crop rotation*: Rotate between crops that are less susceptible to *Sclerotinia* diseases, such as onion or sweetpotato. Note, however, that crop rotation is not very effective because of the wide host range of *Sclerotinia*, and because sclerotia last up to 5 years in the soil.
- *Soil solarisation*: Kill sclerotia (plus other pathogens and weeds) in the top 30 cm of soil by using transparent polyethylene covers. Moisten soil and cover for 4-6 weeks.

During growth:

- *Soil amendment*: Mulch the soil, and incorporate manures into the soil.
- *Reduce crop humidity*: Prevent high humidity within crops. Reduce the time that leaves are wet and susceptible to spore infection by:
 - o Using wider row spacing of plants.
 - o Using a trellis to raise foliage from the ground.
 - o Pruning lower branches.

After harvest:

- *Ploughing*: Where ploughing is practiced, turn in diseased crops immediately after harvest.
- *Harvesting*: Do not harvest and pack (e.g., beans, carrots, celery, potatoes and pumpkin) during wet weather, in order to prevent rots developing during transit and storage.

RESISTANT VARIETIES

Scarlet runner bean is reported to be resistant.

CHEMICAL CONTROL

For seed treatments:

Seed treatments with thiram, captan, thiophanate-methyl, iprodione and procymidone have all been used to reduce *Sclerotinia* wilt.

For field treatments:

It is very unlikely that soil fumigants or foliar fungicides would be used against *Sclerotinia* in Pacific island countries, not only because the disease is relatively rare, but also because of high costs and difficulty of obtaining pesticide products. Foliar fungicides used elsewhere include some in the bendimidazole, strobilurin, triazole and dicarboximide pesticide groups.
