

## Root knot nematodes (127)

### Summary

- Worldwide distribution. In tropics and sub-tropics. Several types. On many vegetables (beans (**see Fact Sheet no. 127**), capsicum, carrot, celery (**see Fact Sheet no. 254**), cucumber, eggplant, ginger, lettuce, potato, tomato and yam), fruit crops (melon, papaya, pineapple), ornamentals, and weeds. Important pests.
- Plants become yellow, stunted, and wilt. Characteristic galls on the roots ('knots').
- Eggs laid in soil, worm-like young females enter the roots to feed and lay eggs, causing cells to swell.
- Spread occurs in soil water, on tools, footwear and machinery, and over long distances in plant roots, especially in the trade in vegetable seedlings and ornamentals.
- Cultural control: resistant varieties; pasteurised soil or use soilless mixes; crop rotation; fallow periods (4-6 months); soil solarisation (4-6 weeks); manures and composts; marigold fallows.
- Chemical control: none recommended.

### Common Name

Root-knot nematodes

### Scientific Name

*Meloidogyne incognita* and other species.

Photo 1. Galls on the roots of *Phaseolus* bean caused by *Meloidogyne* species.

Photo 2. As in Photo 1, galls of *Meloidogyne* sp. on *Phaseolus* bean. Note the galls on the roots of the two plants on the left with smaller root mass compared to the healthy plant on the right.

Photo 4. Root knot nematode, *Meloidogyne* species) galls on parsley.

Photo 3. Root-knot nematode, *Meloidogyne* sp., on ginger. Note that the damage is on the young buds, and that the decay has probably occurred in storage. A healthy rhizome is on the left.
